

SCHEDULING STATUS

S4

1. NAME OF THE MEDICINE

LENVIMA 4 hard capsules

LENVIMA 10 hard capsules

2. QUALITATIVE AND QUANTITATIVE COMPOSITION

LENVIMA 4: Each hard capsule contains lenvatinib mesilate equivalent to 4 mg lenvatinib.

LENVIMA 10: Each hard capsule contains lenvatinib mesilate equivalent to 10 mg lenvatinib.

LENVIMA is sugar free.

For the full list of excipients, see section 6.1.

3. PHARMACEUTICAL FORM

Hard capsules

LENVIMA 4: A yellowish-red body and yellowish-red cap, approximately 14,3 mm in length, marked in black ink with “C” on the cap, and “LENV 4 mg” on the body.

LENVIMA 10: A yellow body and yellowish-red cap, approximately 14,3 mm in length, marked in black ink with “C” on the cap, and “LENV 10 mg” on the body.

4. CLINICAL PARTICULARS

4.1 Therapeutic indications

LENVIMA is indicated for the treatment of adult patients (> 18 years of age) with progressive, locally advanced or metastatic, radioactive iodine (RAI) refractory differentiated thyroid cancer (DTC).

LENVIMA is indicated in combination with everolimus for the treatment of adult patients (> 18 years of age) with advanced renal cell carcinoma whose disease has progressed following one prior vascular endothelial growth factor targeted therapy.

LENVIMA is indicated for the first-line treatment of adult patients (> 18 years of age) with unresectable hepatocellular carcinoma (HCC).

4.2 Posology and method of administration

LENVIMA treatment should be supervised by a healthcare provider experienced in the use of anticancer therapies.

Posology

Starting dose in RAI – Refractory DTC

The recommended dose of LENVIMA is 24 mg (two 10 mg capsules plus one 4 mg capsule) taken once daily. The daily dose is to be modified as needed according to the dose/toxicity management plan (see dose adjustment section below).

Treatment should continue as long as there is clinical benefit or until unacceptable toxicity occurs.

Starting dose in Advanced Renal Cell Carcinoma

The recommended daily dose of LENVIMA is 18 mg (one 10 mg capsule and two 4 mg capsules) once daily in combination with 5 mg everolimus once daily. The daily doses of LENVIMA, and if necessary, everolimus are to be modified as needed according to the dose/toxicity management plan (see dose adjustment section below).

Treatment should continue as long as there is clinical benefit or until unacceptable toxicity occurs.

Starting dose in Hepatocellular Carcinoma

The recommended daily dose of LENVIMA is 8 mg (two 4 mg capsules) once daily for patients with a body weight of < 60 kg and 12 mg (three 4 mg capsules) once daily for patients with a body weight of \geq 60 kg. The daily dose is to be modified, as needed, according to the dose/toxicity management plan (see dose adjustment section below).

Treatment should continue as long as there is clinical benefit or until unacceptable toxicity occurs.

Dose adjustment during therapy

Management of adverse reactions may require dose interruption, adjustment, or discontinuation of LENVIMA or LENVIMA and everolimus if treating in the combination (see section 4.4).

Medical management of nausea, vomiting and diarrhoea should be optimised to reduce the risk of dehydration and renal failure (see section 4.4) prior to any LENVIMA therapy interruption or dose reduction.

For toxicities thought to be related to LENVIMA, general advice about dose management is included in Table 1, and specific daily dose modifications are in Table 2.

For toxicities thought to be related to everolimus, when treating renal cell carcinoma using the combination of LENVIMA and everolimus, everolimus treatment should be interrupted, reduced to alternate day dosing, or discontinued (see the everolimus PI for advice on specific adverse reactions).

For toxicities thought to be related to both LENVIMA and everolimus, when treating renal cell carcinoma using the combination, LENVIMA (see Table 1) should be reduced prior to reducing everolimus.

Grades are based on the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE).

Table 1 Dose modifications for adverse reactions

| Adverse Reaction | CTCAE Grade | Action | Dose reduce and resume LENVIMA |
|-----------------------------|----------------------|-------------|---|
| Hypertension | Grade 3 ^a | Interrupt | Resolves to Grade 0, 1 or 2. See detailed guidance in Table 3 in section 4.4 Special warnings and precautions for use, Hypertension section |
| | Grade 4 | Discontinue | Do not resume |
| Proteinuria | ≥2 gm/24 hours | Interrupt | Resolves to less than 2 gm/24 hours |
| Nephrotic syndrome | ---- | Discontinue | Do not resume |
| Renal impairment or failure | Grade 3 | Interrupt | Resolves to Grade 0-1 or baseline |
| | Grade 4 ^b | Discontinue | Do not resume |
| Cardiac failure | Grade 3 | Interrupt | Resolves to Grade 0-1 or baseline |
| | Grade 4 | Discontinue | Do not resume |
| PRES/RPLS | Any grade | Interrupt | Consider resuming at reduced dose if resolves to Grade 0-1 |
| Hepatotoxicity | Grade 3 | Interrupt | Resolves to Grade 0-1 or baseline |
| | Grade 4 ^b | Discontinue | Do not resume |
| Arterial thromboembolisms | Any Grade | Discontinue | Do not resume |
| | Grade 3 | Interrupt | Resolves to Grade 0-1 |

| | | | |
|-----------------------------------|----------------------|-------------|-----------------------------------|
| Haemorrhage and Thrombocytopenia* | Grade 4 | Discontinue | Do not resume |
| GI perforation or fistula | Grade 3 | Interrupt | Resolves to Grade 0-1 or baseline |
| | Grade 4 | Discontinue | Do not resume |
| QT interval prolongation | >500 ms | Interrupt | Resolves to < 480 ms or baseline |
| Diarrhoea | Grade 3 | Interrupt | Resolves to Grade 0-1 or baseline |
| | Grade 4 ^c | Discontinue | Do not resume |

^a Grade 3 despite optimal antihypertensive therapy.

^b Grade 4 laboratory abnormalities judged to be non-life-threatening, may be managed as severe reactions (e.g., Grade 3)

^c Grade 4 despite medical management

Table 2 Recommended Dosage Reductions of LENVIMA for Adverse Reactions

| Indication | First dosage reduction to | Second dosage reduction to | Third dosage reduction to |
|--------------------------------|----------------------------------|-----------------------------------|----------------------------------|
| DTC | 20 mg once daily | 14 mg once daily | 10 mg once daily |
| RCC | 14 mg once daily | 10 mg once daily | 8 mg once daily |
| HCC | | | |
| Actual weight 60 kg or greater | 8 mg once daily | 4 mg once daily | 4 mg every other day |
| Actual weight less than 60 kg | 4 mg once daily | 4 mg every other day | Discontinue |

Special populations

Dosage adjustment in hepatic impairment

DTC, RCC and HCC

No dose adjustment is recommended for patients with DTC or RCC and mild or moderate hepatic impairment (Child-Pugh A or B). Lenvatinib concentrations may increase in patients with DTC or RCC and severe hepatic impairment (Child-Pugh C). Reduce the dose for patients with DTC or RCC and severe hepatic impairment. In patients with severe (Child-Pugh C) hepatic impairment, the recommended starting dose for RAI - Refractory DTC is 14 mg LENVIMA taken once daily and for RCC is 10 mg of LENVIMA taken once daily in combination with the dose of everolimus recommended for patients with severe hepatic impairment in the everolimus PI. Further dose adjustments may be necessary on the basis of individual tolerability.

No dose adjustment is recommended for patients with HCC and mild hepatic impairment (Child-Pugh A). There is no recommended dose for patients with HCC with moderate or severe hepatic impairment.

Dosage adjustment in renal impairment

DTC and RCC

No adjustment of the starting dose is required on the basis of renal function in patients with mild (CrCL 60 -89 mL/min) or moderate (CrCL 30-59 mL/min) renal impairment. In patients with severe renal impairment (CrCL <30 mL/min), the recommended starting dose for thyroid cancer is 14 mg LENVIMA taken once daily and for renal cell carcinoma is 10 mg of LENVIMA plus 5 mg everolimus taken once daily. Further dose adjustments may be necessary based on the individual tolerability. Patients with end-stage renal disease were not studied, therefore the use of LENVIMA in these patients is not recommended.

Patients with hypertension

Blood pressure should be well controlled prior to treatment with LENVIMA and should be regularly monitored during treatment (see sections 4.4 and 4.8).

Use in the elderly

No adjustment of the starting dose is required on the basis of age. Limited data are available on the use in patients aged ≥ 75 years.

Paediatric population

The safety and efficacy of LENVIMA in children <18 years have not yet been established (see section 5.1).

Method of administration

LENVIMA should be taken at about the same time each day, with or without food. The capsules should be swallowed whole with water.

If unable to swallow the capsule whole place the capsule, without breaking or crushing, in a glass of approximately 25 mL of water or apple juice. The capsules must be left to disintegrate in the liquid for at least 10 minutes and then gently stirred for at least 3 minutes to dissolve the capsules shells. The suspension is to be swallowed. After drinking, the same amount of water or apple juice (25 mL) must be added to the glass and swirled a few times. The additional liquid must be swallowed. Do not mix more than one medicine in the glass at the same time.

The person preparing the suspension should ensure their hands are thoroughly washed on completion of preparation and taking of the medication.

If a patient misses a dose, and it cannot be taken within 12 hours, then that dose should be skipped and the next dose should be taken at the usual time of administration.

4.3 Contraindications

Hypersensitivity to LENVIMA or to any of the excipients listed in section 6.1.

Patients with fistula(e), and/or patients at risk of developing fistula(e), such as after a major surgical procedure.

Patients with severe and/or uncontrolled hypertension (BP \leq 150 mmHg, diastolic BP \leq 95 mmHg).

Patients with severe thrombocytopenia ($< 50 \times 10^3$ per μ L) and/or active bleeding.

Patients due to undergo surgery or radiotherapy.

4.4 Special warnings and precautions for use

Gastrointestinal toxicity: Diarrhoea and dehydration

Diarrhoea has been reported frequently in patients treated with LENVIMA usually occurring early in the course of treatment (see section 4.8). Prompt medical management of diarrhoea should be instituted in order to prevent dehydration. LENVIMA should be discontinued in the event of persistent Grade 4 diarrhoea despite medical management (see section 4.2).

Gastrointestinal toxicity (including diarrhoea, nausea and vomiting) should be actively managed in order to reduce the risk of development of complications such as dehydration, electrolyte imbalances, and possible renal impairment or renal failure. Serious adverse events of both hypokalaemia and hyperkalaemia have occurred, as such, renal function and electrolytes should be monitored closely (see section 4.4 below).

Renal failure and impairment

Patients with baseline renal function <60 mL/minute experienced more adverse events, including fatal and serious adverse events of Grade 3 or 4, than those with normal renal function and were more likely to require a treatment interruption, dose reduction or discontinuation of treatment. The recommended starting dose is lower for patients with renal impairment (see section 4.2) and it is also recommended these patients be monitored closely during treatment. There is no clinical trial experience of patients with severe renal impairment.

Renal impairment (including renal failure) has been reported in patients treated with LENVIMA (see section 4.8). The primary risk factors identified were pre-existing renal impairment and dehydration and/or hypovolemia due to gastrointestinal toxicity (see section 4.4 below). Caution should be taken in patients receiving agents acting

on the renin-angiotensin aldosterone system given a potentially higher risk for acute renal failure with the combination treatment. Dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2).

If patients have severe renal impairment, the initial dose of LENVIMA should be adjusted (see section 4.2).

Hypertension

Hypertension has been reported in patients treated with LENVIMA, usually occurring early in the course of treatment (see section 4.8). Blood pressure (BP) should be well controlled prior to treatment with LENVIMA and, if patients are known to be hypertensive, they should be on a stable dose of an antihypertensive therapy for at least 1 week prior to treatment with LENVIMA. The early detection and effective management of hypertension are important to minimise the need for LENVIMA dose interruptions and reductions. Serious complications of poorly controlled hypertension, including aortic dissection, have been reported. Antihypertensives should be started as soon as elevated BP is confirmed. Blood pressure should be monitored after 1 week of treatment with LENVIMA, then every 2 weeks for the first 2 months and monthly thereafter. The choice of antihypertensive treatment should be individualised to the patient's clinical circumstances and follow standard medical practice. For previously normotensive subjects, monotherapy with one of the classes of antihypertensives should be started when elevated BP is observed. For those patients already on antihypertensive medication, the dose of the current medicine may be increased, if appropriate, or one or more medicines of a different class of antihypertensive should be added. When necessary, manage hypertension as recommended in Table 3.

Table 3 Recommended management of hypertension

| Blood pressure (BP) level | Recommended action |
|--|---|
| Systolic BP \geq 140 mmHg up to $<$ 160 mmHg or diastolic BP \geq 90 mmHg up to $<$ 100 mmHg | Continue LENVIMA and initiate antihypertensive therapy, if not already receiving or |

| | |
|--|--|
| | Continue LENVIMA and increase the dose of the current antihypertensive therapy or initiate additional antihypertensive therapy |
| Systolic BP \geq 160 mmHg or diastolic BP \geq 100 mmHg despite optimal antihypertensive therapy | 1. Withhold LENVIMA 2. When systolic BP \leq 150 mmHg, diastolic BP \leq 95 mmHg, and patient has been on a stable dose for at least 48 hours, resume LENVIMA at a reduced dose (see section 4.2) |
| Life-threatening consequences (malignant hypertension, neurological deficit, or hypertensive crisis) | Urgent intervention is indicated. Discontinue LENVIMA and institute appropriate medical management. |

Proteinuria

Proteinuria has been reported in patients treated with LENVIMA, usually occurring early in the course of the treatment (see section 4.8). Monitor urine protein regularly. If urine dipstick proteinuria \geq 2+ is detected, dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2). LENVIMA should be discontinued in the event of nephrotic syndrome.

Cardiac dysfunction

Cardiac failure and decreased left ventricular ejection fraction have been reported in patients treated with LENVIMA (see section 4.8). Patients should be monitored for clinical symptoms or signs of cardiac decompensation, as dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2).

LENVIMA has not been studied in patients who have had cardiac failure within the previous 6 months and therefore should be used with caution in such patients.

Posterior reversible encephalopathy syndrome (PRES) / Reversible posterior leucoencephalopathy syndrome (RPLS)

Posterior reversible encephalopathy syndrome (PRES, also known as RPLS) has been reported in patients treated with LENVIMA (observed in < 1 % of patients; ADVERSE EFFECTS, Selected Adverse Reactions). PRES is a neurological disorder which can present with headache, seizure, lethargy, confusion, altered mental function, blindness, and other visual or neurological disturbances. Mild to severe hypertension may be present. Magnetic resonance imaging is necessary to confirm the diagnosis of PRES. Appropriate measures should be taken to control blood pressure (see section 4.4 above). In patients with signs or symptoms of PRES, dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2).

Hepatotoxicity

In DTC and RCC, liver-related adverse reactions most commonly reported in patients treated with LENVIMA included increases in alanine aminotransferase (ALT), increases in aspartate aminotransferase (AST), and increases in blood bilirubin (see section 4.8). Hepatic failure and acute hepatitis (observed in < 1% of patients) have been reported in patients with DTC and RCC treated with LENVIMA. The hepatic failure events were generally reported in patients with progressive metastatic liver disease.

Liver-related adverse reactions including hepatic encephalopathy and hepatic failure (including fatal reactions) were reported at a higher frequency in LENVIMA treated HCC patients (see section 4.8) compared to DTC and RCC patients. Patients with worse hepatic impairment and/or greater liver tumour burden at baseline had a higher risk of developing hepatic encephalopathy and hepatic failure. Hepatic encephalopathy also occurred more frequently in patients aged 75 years and older. Approximately half of the events of hepatic failure were reported in patients with disease progression.

Liver function tests should be monitored before initiation of treatment, then every 2 weeks for the first 2 months and monthly thereafter during treatment. Patients with HCC should be monitored for worsening liver function including hepatic encephalopathy. In the case of hepatotoxicity, dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2).

If patients have any degree of liver impairment, they need to be monitored closely for liver related adverse reactions. For DTC and RCC patients with severe hepatic impairment, the initial dose of LENVIMA should be adjusted. The available data do not allow for a dosing recommendation for patients with HCC and moderate hepatic impairment (Child-Pugh B). LENVIMA has not been studied in patients with HCC and severe hepatic impairment (Child-Pugh C) and therefore the use of LENVIMA in these patients is not recommended.

Arterial thromboembolic events

Arterial thromboembolic events (cerebrovascular accident, transient ischaemic attack, and myocardial infarction) have been reported in patients treated with LENVIMA (see section 4.8). LENVIMA has not been studied in patients who have had an arterial thromboembolic event within the previous 6 months and therefore should be used with caution in such patients. A treatment decision should be made based upon an assessment of the individual patient's benefit/risk LENVIMA should be discontinued following an arterial thrombotic event (see section 4.2).

Haemorrhagic events and thrombocytopenia

Serious haemorrhagic events have been reported in patients treated with LENVIMA. The most frequently reported haemorrhagic event was mild epistaxis. Serious events of thrombocytopenia have also been reported in patients treated with LENVIMA and thrombocytopenia may increase risk of developing haemorrhagic events. (see section 4.8)

Serious tumour related bleeds have been reported, including fatal haemorrhagic events in LENVIMA treated patients and there have been reports of haemorrhage associated with thrombocytopenia.

The degree of tumour invasion/infiltration of major blood vessels (e.g. carotid artery) should be considered because of the potential risk of severe haemorrhage associated with tumour shrinkage/necrosis following LENVIMA therapy. In the case of haemorrhagic events/ thrombocytopenia, dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2).

Wound healing complications

No formal studies of the effect of LENVIMA on wound healing have been conducted. Impaired wound healing has been reported in patients receiving LENVIMA. Temporary interruption of LENVIMA should be considered in patients undergoing major surgical procedures. There is limited clinical experience regarding the timing of reinitiation of LENVIMA following a major surgical procedure. Therefore, the decision to resume LENVIMA following a major surgical procedure should be based on clinical judgment of adequate wound healing.

Gastrointestinal perforation and fistula formation

Gastrointestinal perforation or fistulae have been reported in patients treated with LENVIMA (see section 4.8). In most cases, gastrointestinal perforation and fistulae occurred in patients with risk factors such as prior surgery or radiotherapy. In the case of a gastrointestinal perforation or fistula, dose interruptions, adjustments, or discontinuation may be necessary (see section 4.2).

Non-gastrointestinal fistula

Patients may be at increased risk for the development of fistulae when treated with LENVIMA. Cases of fistula formation or enlargement that involve other areas of the body than stomach or intestines were observed in clinical trials and in post-marketing experience (e.g. tracheal, tracheo-oesophageal, oesophageal, cutaneous, female genital tract fistulae). In addition, pneumothorax has been reported with and without clear evidence of a

bronchopleural fistula. Some reports of gastrointestinal perforation, fistula and pneumothorax occurred in association with tumour regression or necrosis. Prior surgery and radiotherapy may be contributing risk factors. LENVIMA should not be started in patients with fistulae to avoid worsening and LENVIMA should be permanently discontinued in patients with oesophageal or tracheobronchial tract involvement and any Grade 4 fistula (see section 4.2); limited information is available on the use of dose interruption or reduction in management of other events, but worsening was observed in some cases and caution should be taken. LENVIMA may adversely affect the wound healing process as do other medicines of the same class.

QT interval prolongation

The incidence of QT/QTc interval prolongation was higher in patients treated with LENVIMA than in patients treated with placebo (see section 4.8). The median time to onset of QTc prolongation was 16,1 weeks in the DTC study, 31,1 weeks in the HCC study for patients on LENVIMA monotherapy and 30 weeks in the RCC study for combination patients. Electrocardiograms should be monitored in patients on an ongoing basis with a special attention for those with congenital long QT syndrome, congestive heart failure, bradydysrhythmias, and those taking drugs known to prolong the QT interval, including Class Ia and III antiarrhythmics. LENVIMA should be withheld in the event of development of QT interval prolongation greater than 500 ms. LENVIMA should be resumed at a reduced dose when QTc prolongation is resolved to < 480 ms or baseline (see section 4.2).

Electrolyte disturbances such as hypokalaemia, hypocalcaemia, or hypomagnesaemia increase the risk of QT prolongation; therefore electrolyte abnormalities should be monitored and corrected in all patients before starting treatment. Periodic monitoring of ECG and electrolytes (magnesium, potassium and calcium) should be considered during treatment. Blood calcium levels should be monitored at least monthly and calcium should be replaced as necessary during LENVIMA treatment. LENVIMA dose should be interrupted or dose adjusted as necessary depending on severity, presence of ECG changes, and persistence of hypocalcaemia.

Impairment of thyroid stimulating hormone suppression/Thyroid dysfunction

LENVIMA impairs exogenous thyroid suppression (see section 4.8).

Hypothyroidism has been reported as very common in patients treated with LENVIMA in the RCC trial (see section 4.8).

Thyroid function should be monitored before initiation of treatment, and periodically at least monthly throughout treatment with LENVIMA. Hypothyroidism should be treated according to standard medical practice to maintain euthyroid state.

Special Populations

Limited data are available for patients of ethnic origin other than Caucasian or Asian. LENVIMA should be used with caution in such patients, given the reduced tolerability of LENVIMA in Asian patients (see section 4.8).

There are no data on the use of LENVIMA immediately following sorafenib or other anticancer treatments and there may be a potential risk for additive toxicities unless there is an adequate washout period between treatments.

The minimal washout period in clinical trials was of 4 weeks.

4.5 Interaction with other medicines and other forms of interaction

Effect of other medicines on LENVIMA

CYP3A, P-gp, and BCRP inhibitors or inducers

LENVIMA may be administered regardless of co-administration with CYP3A, P-gp, and BCRP inhibitors. In healthy subjects, ketoconazole (400 mg for 18 days) increased lenvatinib (administered as a single dose on Day 5) AUC_{0-inf} and AUC_{0-t} approximately 15 % while C_{max} increased 19 %. This is supported by a population PK analysis which found CYP3A4 inhibitors decreased Cl/F by 7,8 %.

LENVIMA may be co-administered without dose adjustment with CYP3A and P-gp inducers, based on a study in which healthy subjects were administered repeated doses of rifampicin (600 mg for 21 days) and a single dose of lenvatinib (24 mg, Day 15).

AUC_{0-inf} and AUC_{0-t} decreased approximately 18 % while C_{max} did not change. The effect of CYP3A induction alone was estimated by comparing the PK parameters for lenvatinib following single and multiple doses of rifampicin. Lenvatinib AUC and C_{max} were predicted to decrease by 30 % and 15 %, respectively, after strong induction in the absence of acute P-gp inhibition. This is supported by a population PK analysis which found CYP3A4 inducers increased Cl/F by 30 %.

Gastric pH-altering medicines

In a population pharmacokinetic analysis of patients receiving LENVIMA up to 24 mg once daily, medicines which increase gastric pH (H₂ receptor blockers, proton pump inhibitors, antacids) did not have a significant effect on lenvatinib exposure.

Other chemotherapeutic medicines

Concomitant administration of lenvatinib (e.g. LENVIMA), carboplatin, and paclitaxel had no significant impact on the pharmacokinetics of any of these 3 substances.

Effect of LENVIMA on other medicines

Cytochrome P450 or UGT enzyme substrates

Lenvatinib (e.g. LENVIMA) is considered neither a strong inhibitor nor an inducer of cytochrome P450 or uridine 5'-diphosphoglucuronosyl transferase (UGT) enzymes.

P-gp and BCRP substrates

Lenvatinib as contained in LENVIMA showed minimal inhibitory activities toward P-gp-mediated and BCRP-mediated transport activities. Similarly, no induction of P-gp mRNA expression was observed.

OAT, OCT, OATP, BSEP, MATE and aldehyde oxidase substrates

Lenvatinib showed inhibitory effects on organic anion transporter (OAT)1, OAT3, organic cation transporter (OCT)1, OCT2, organic anion transporting polypeptide (OATP)1B1, and bile salt export pump (BSEP), but minimal or no inhibitory effect on OATP1B3 and multidrug and toxin extrusion 2 (MATE2)-K. Lenvatinib weakly inhibits MATE1. In human liver cytosol, lenvatinib did not inhibit aldehyde oxidase activity.

4.6 Fertility, pregnancy and lactation

Women of childbearing potential / Contraception in males and females

Women of childbearing potential should avoid becoming pregnant and use highly effective contraception while on treatment with LENVIMA and for at least one month after finishing treatment. It is currently unknown whether LENVIMA may reduce the effectiveness of hormonal contraceptives, and therefore women using oral hormonal contraceptives should add a barrier method.

Pregnancy

LENVIMA should not be used during pregnancy.

There is limited information on the use of LENVIMA in pregnant women. Lenvatinib was embryotoxic and teratogenic when administered to rats and rabbits during organogenesis at exposures below the clinical exposure (based on body surface area) at the maximum recommended human dose. Foetal anomalies included parietal oedema, cryptophthalmia, abnormal tail (rats), retroesophageal subclavian artery, fused ribs, and vertebral abnormalities (rabbits). These embryofoetal findings are probably related to the pharmacologic activity of lenvatinib as an antiangiogenic medicine.

Breastfeeding

LENVIMA should not be used during breastfeeding.

It is not known whether LENVIMA is excreted in human milk. Lenvatinib and its metabolites are excreted in rat milk and neonatal rats were more sensitive to the toxicity of lenvatinib compared to adults (see section 4.4).

Fertility

Effects in humans are unknown. However, testicular and ovarian toxicity has been observed in rats, dogs, and monkeys.

No specific studies with lenvatinib have been conducted in animals to evaluate the effect on fertility. However, testicular and ovarian changes were observed in repeated-dose toxicity studies in animals at exposures 11 to 15 times (rat) or 0,6 to 7 times (monkey) the anticipated clinical exposure (based on AUC) at the maximum tolerated human dose. These findings were reversible at the end of a 4-week recovery period.

4.7 Effects on ability to drive and use machines

No studies on the effects on the ability to drive and use machines have been performed.

LENVIMA may cause side effects such as fatigue and dizziness. Patients who experience these symptoms should be cautious when driving or operating machines.

4.8 Undesirable effects

Summary of the safety profile (DTC, RCC and HCC)

The safety profile of LENVIMA is based on the combined safety data of 62 RCC patients in combination with everolimus, 452 DTC patients and 496 HCC patients; allowing characterisation of common adverse drug reactions in DTC, RCC and HCC patients. The adverse reactions presented in this section are based on safety data of DTC, RCC and HCC patients.

Tabulated list of adverse reactions for DTC, RCC and HCC studies

Similar adverse reactions were observed in clinical trials in DTC, RCC and HCC. Adverse reactions that occur more frequently with combination therapy compared to LENVIMA monotherapy are hypothyroidism, (including increased blood thyroid stimulating hormone), hypercholesterolaemia, and severe diarrhoea. Table 4 shows the frequency categories of adverse reactions observed in clinical trials for DTC, RCC and HCC, and reported from post-marketing use of LENVIMA. The adverse reaction frequency category represents the most conservative estimate of frequency from the three individual populations.

Frequencies are defined as:

- Very common ($\geq 1/10$)
- Common ($\geq 1/100$ to $< 1/10$)
- Uncommon ($\geq 1/1,000$ to $< 1/100$)
- Not known (cannot be estimated from the available data)

Table 4 Adverse reactions reported in patients in clinical trials (DTC, RCC, HCC)

| System Organ Class (MedDRA terminology [*]) | Very common | Common | Uncommon | Not known |
|---|---|---|--------------------|-----------|
| Infections and infestation | Urinary tract infection | | Perineal abscess | |

*: Preferred terms have been reassigned to the SOC most relevant to the target organ.

** : These adverse reactions occur more frequently with combination therapy compared to LENVIMA monotherapy.

†: Includes cases with a fatal outcome.

‡: See section 4.8 Description of selected adverse reactions for further characterisation.

The following terms have been combined:

a: Thrombocytopenia includes thrombocytopenia and decreased platelet count. Neutropenia includes neutropenia and decreased neutrophil count decreased. Leukopenia includes leukopenia and decreased white blood cell count. Lymphopenia includes lymphopenia and decreased lymphocyte count.

b: Hypomagnesaemia includes hypomagnesaemia and decreased blood magnesium. Hypercholesterolaemia includes hypercholesterolaemia and increased blood cholesterol.

c: Myocardial infarction includes myocardial infarction and acute myocardial infarction.

d: Haemorrhage includes all haemorrhage terms such as epistaxis, haemoptysis, haematuria, contusion, haematochezia, gingival bleeding, petechiae, pulmonary haemorrhage, rectal haemorrhage, blood urine present, haematoma, vaginal haemorrhage, conjunctival haemorrhage, haemorrhoidal haemorrhage, intracranial tumour haemorrhage, laryngeal haemorrhage, ecchymosis, increased tendency to bruise, post procedural haemorrhage, purpura, skin haemorrhage, aneurysm ruptured, arterial haemorrhage, eye haemorrhage, gastric haemorrhage, gastroduodenitis haemorrhagic, gastrointestinal haemorrhage, haematemesis, haemorrhage, haemorrhagic stroke, melaena, metrorrhagia, nail bed bleeding, haemothorax, postmenopausal haemorrhage, proctitis haemorrhagic, renal haematoma, splenic haemorrhage, splinter haemorrhages, subarachnoid haemorrhage, tracheal haemorrhage, tumour haemorrhage.

Haemorrhage terms that occurred in 5 or more subjects with DTC were: epistaxis, haemoptysis, haematuria, contusion, haematochezia, gingival bleeding, petechial, pulmonary haemorrhage, rectal haemorrhage, blood urine present, haematoma and vaginal haemorrhage.

Haemorrhage terms that occurred in 5 or more subjects with HCC were: epistaxis, haematuria, gingival bleeding, haemoptysis, oesophageal varices haemorrhage, haemorrhoidal haemorrhage, mouth haemorrhage, rectal haemorrhage and upper gastrointestinal haemorrhage.

e: Hypertension includes: hypertension, hypertensive crisis, increased blood pressure diastolic, orthostatic hypertension and increased blood pressure.

f: Gastrointestinal and abdominal pain includes: abdominal discomfort, abdominal pain, lower abdominal pain, upper abdominal pain, abdominal tenderness, epigastric discomfort, and gastrointestinal pain.

g: Oral inflammation includes: aphthous stomatitis, aphthous ulcer, gingival erosion, gingival ulceration, oral mucosal blistering, stomatitis, glossitis, mouth ulceration, and mucosal inflammation.

h: Oral pain includes: oral pain, glossodynia, gingival pain, oropharyngeal discomfort, oropharyngeal pain and tongue discomfort

- i: Pancreatitis includes: pancreatitis and acute pancreatitis.
- j: Increased blood bilirubin includes: hyperbilirubinaemia, increased blood bilirubin, jaundice and increased bilirubin conjugated. Hypoalbuminaemia includes hypoalbuminaemia and decreased blood albumin.
- k: Hepatic failure includes: hepatic failure, acute hepatic failure and chronic hepatic failure.
- l: Hepatic encephalopathy includes: hepatic encephalopathy, coma hepatic, metabolic encephalopathy and encephalopathy.
- m: Hepatocellular damage and hepatitis includes: drug-induced liver injury, hepatic steatosis, and cholestatic liver injury.
- n: Renal failure cases includes: acute prerenal failure, renal failure, renal failure acute, acute kidney injury and renal tubular necrosis.
- o: Non-gastrointestinal fistula includes cases of fistula occurring outside of the stomach and intestines such as tracheal, tracheo-oesophageal, oesophageal, female genital tract fistula, and cutaneous fistula.

Clinical trials

Radioactive iodine refractory differentiated thyroid cancer

The safety of LENVIMA was evaluated in 392 patients from the Phase 3 SELECT trial with radioactive iodine-refractory differentiated thyroid cancer (RAI-refractory DTC) randomised to receive LENVIMA 24 mg once daily (n=261) or placebo (n=131) (see section 5.1).

In the SELECT study, the most common adverse reactions observed in LENVIMA-treated patients (greater than or equal to 30 %) were, in order of decreasing frequency, hypertension, fatigue, diarrhoea, arthralgia/myalgia, decreased appetite, weight decreased, nausea, stomatitis, headache, vomiting, proteinuria, palmar-plantar erythrodysesthesia (PPE) syndrome, abdominal pain, and dysphonia. The most common serious adverse reactions (at least 2 %) were pneumonia (4 %), hypertension (3 %), and dehydration (3 %).

Adverse reactions led to dose reductions in 68 % of patients receiving LENVIMA and 5 % of patients receiving placebo; 18 % of patients discontinued LENVIMA and 5 % discontinued placebo for adverse reactions. The most common adverse reactions (at least 10 %) resulting in dose reductions of LENVIMA were hypertension (13 %), proteinuria (11 %), decreased appetite (10 %), and diarrhoea (10 %); the most common adverse reactions (at least 1 %) resulting in discontinuation of LENVIMA were hypertension (1 %) and asthenia (1 %).

Table 5 presents the incidence rates of treatment-emergent adverse events observed in the double-blind phase of the DTC study. All adverse events occurring with a treatment difference of at least 5 % over placebo are included in the Table. Clinically significant events (CSEs) that were observed more frequently than placebo are also included based on an assessment of the known pharmacology of LENVIMA and class effects.

Table 5 Treatment-Emergent Adverse Events reported for LENVIMA in the double-blind phase of the DTC Study*

| System Organ Class (MedDRA terminology) | LENVIMA 24 mg N=261 | |
|---|------------------------|-------------------|

Renal cell carcinoma

The most common adverse reactions observed in the LENVIMA in combination with everolimus-treated group (> 30 %) were, in order of decreasing frequency, diarrhoea, fatigue, arthralgia/myalgia, decreased appetite,

vomiting, nausea, stomatitis/oral inflammation, hypertension, peripheral oedema, cough, abdominal pain, dyspnoea, rash, weight decreased, haemorrhagic events, and proteinuria. The most common serious adverse reactions ($\geq 5\%$) were renal failure (11%), dehydration (10%), anaemia (6%), thrombocytopenia (5%), diarrhoea (5%), vomiting (5%), and dyspnoea (5%).

Adverse reactions led to dose reductions or interruption in 89% of patients receiving LENVIMA + everolimus and 54% in patients receiving everolimus. The most common adverse reactions ($\geq 5\%$) resulting in dose reductions in the LENVIMA + everolimus-treated group were diarrhoea (21%), fatigue (8%), thrombocytopenia (6%), vomiting (6%), nausea (5%), and proteinuria (5%).

Treatment discontinuation due to an adverse reaction occurred in 29% of patients in the LENVIMA + everolimus-treated group and 12% of patients in the everolimus-treated group.

Table 6 presents the adverse reactions in $> 15\%$ of patients in the LENVIMA + Everolimus arm.

| Table 6 Grades 1-4 Adverse Events in $> 15\%$ of Patients in the LENVIMA +Everolimus Arm | | | | |

| Lymphocyte count decreased | 10 | 20 |

- a) With at least 1 grade increase from baseline
- b) Subject with at least 1 post baseline laboratory value

Hepatocellular Carcinoma

The safety of LENVIMA was evaluated in REFLECT, which randomised (1:1) patients with unresectable hepatocellular carcinoma (HCC) to LENVIMA (n=476) or sorafenib (n=475) (see section 5.1). The dose of LENVIMA was 12 mg orally once daily for patients with a baseline body weight of ≥ 60 kg and 8 mg orally once daily for patients with a baseline body weight of < 60 kg.

The most common adverse reactions observed in the LENVIMA-treated patients (≥ 20 %) were, in order of decreasing frequency, hypertension, fatigue, diarrhoea, decreased appetite, arthralgia/myalgia, decreased weight, abdominal pain, palmar-plantar erythrodysesthesia syndrome, proteinuria, dysphonia, haemorrhagic events, hypothyroidism, and nausea. The most common serious adverse reactions (≥ 2 %) in LENVIMA-treated patients were hepatic encephalopathy (5 %), hepatic failure (3 %), ascites (3 %), and decreased appetite (2 %).

Adverse reactions led to dose reduction or interruption in 62 % of patients receiving LENVIMA. The most common adverse reactions (≥ 5 %) resulting in dose reduction or interruption of LENVIMA were fatigue (9 %), decreased appetite (8 %), diarrhoea (8 %), proteinuria (7 %), hypertension (6 %), and palmar-plantar erythrodysesthesia syndrome (5 %).

Treatment discontinuation due to adverse reactions occurred in 20 % of patients in the LENVIMA-treated group. The most common adverse reactions (≥ 1 %) resulting in discontinuation of LENVIMA were fatigue (1 %), hepatic encephalopathy (2 %), hyperbilirubinemia (1 %), and hepatic failure (1 %).

Table 8 summarises the adverse reactions that occurred in ≥ 10 % of patients receiving LENVIMA in REFLECT.

Table 10 Post-marketing adverse drug reactions

The following adverse reactions have been identified during post approval use of LENVIMA. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to medicine exposure.

| | |
|--|---|
| Gastrointestinal disorders: | increased amylase, increased lipase, pancreatitis |
| Hepatobiliary disorders: | cholecystitis |
| General disorders and administration site conditions: | impaired healing |
| Renal and urinary disorders: | nephrotic syndrome |
| Respiratory, thoracic and mediastinal disorders: | pneumothorax |
| Vascular Disorders: | aortic dissection |

Reporting of suspected adverse reactions

Reporting suspected adverse reactions after authorisation of the medicine is important. It allows continued monitoring of the benefit/risk balance of the medicine. Healthcare providers are asked to report any suspected adverse reactions to SAHPRA via the “**6.04 Adverse Drug Reactions Reporting Form**”, found online under SAHPRA’s publications: <https://www.sahpra.org.za/Publications/Index/8>.

4.9 Overdose

There have been reports of overdose with LENVIMA including a single administration of 144 mg, 6 times the recommended daily dose. These cases were associated with adverse reactions consistent with the known safety profile of LENVIMA or were without adverse reactions. Death due to multiorgan dysfunction occurred in a patient who received a single dose of LENVIMA 120 mg orally. There is no specific antidote for overdose with LENVIMA, due to the high plasma protein binding, lenvatinib is not expected to be dialysable. In case of suspected overdose, LENVIMA should be withheld and appropriate supportive care given as required.

5. PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

Pharmacotherapeutic group: antineoplastic agents, protein kinase inhibitors, ATC code: L01XE29

Mechanism of action

Lenvatinib is a multiple receptor tyrosine kinase (RTK) inhibitor that inhibits the kinase activities of vascular endothelial growth factor (VEGF) receptors VEGFR1 (FLT1), VEGFR2 (KDR), and VEGFR3 (FLT4), in addition to other proangiogenic and oncogenic pathway-related RTKs including fibroblast growth factor (FGF) receptors FGFR1, 2, 3, and 4, the platelet derived growth factor (PDGF) receptor PDGFR α , KIT, and RET.

In addition, lenvatinib inhibited the proliferation of human hepatocellular carcinoma (HCC) cell lines dependent on FGFR signalling *in vitro* and caused a concurrent inhibition of FGF-receptor substrate 2 α (FRS2 α) phosphorylation.

The combination of lenvatinib and everolimus showed increased antiangiogenic and anti-tumour activity as demonstrated by decreased human endothelial cell proliferation, tube formation, and VEGF signalling *in vitro* and tumour volume in mouse xenograft models of human renal cell cancer greater than each medicine alone.

Pharmacodynamic effects

Cardiac electrophysiology

A single 32-mg dose of lenvatinib did not prolong the QT/QTc interval based on results from a thorough QT study in healthy volunteers; however, QT/QTc interval prolongation has been reported at a higher incidence in patients treated with LENVIMA than in patients treated with placebo (see section 4.8).

Clinical trials

Radioactive iodine refractory differentiated thyroid cancer

The SELECT study was a multicentre, randomised, double-blind, placebo-controlled trial that was conducted in 392 patients with radioactive iodine refractory differentiated thyroid cancer with independent, centrally reviewed, radiographic evidence of disease progression within 12 months (+1 month window) prior to enrolment. Radioiodine-refractory status was defined as one or more measurable lesions either with a lack of iodine uptake or with progression in spite of radioactive-iodine (RAI) therapy or having a cumulative activity of RAI of >600 mCi or 22 GBq with the last dose at least 6 months prior to study entry.

Randomisation was stratified by geographic region (Europe, North America, and Other), prior VEGF/VEGFR-targeted therapy (patients may have received 0 or 1 prior VEGF/VEGFR-targeted therapy), and age (≤ 65 years or >65 years). The main efficacy outcome measure was progression-free survival (PFS) as determined by blinded independent radiologic review using Response Evaluation Criteria in Solid Tumours (RECIST) 1.1.

Secondary efficacy outcome measures included overall response rate and overall survival (OS). Patients in the placebo arm could opt to receive LENVIMA treatment at the time of confirmed disease progression.

Eligible patients with measurable disease according to RECIST 1.1 were randomised 2:1 to receive LENVIMA 24 mg once daily (n=261) or placebo (n=131). Baseline demographics and disease characteristics were well balanced for both treatment groups. Of the 392 patients randomised, 76,3% were naïve to prior VEGF/VEGFR-targeted therapies, 49,0 % were female, 49,7 % were European, and the median age was 63 years. Histologically, 66,1 % had a confirmed diagnosis of papillary thyroid cancer and 33,9 % had follicular thyroid cancer which included Hürthle cell 14,8 % and clear cell 3,8 %. Metastases were present in 99 % of the patients: lungs in 89,3 %, lymph nodes in 51,5 %, bone in 38,8 %, liver in 18,1 %, pleura in 16,3 %, and brain in 4,1 %. The majority of patients (54 %) had an Eastern Cooperative Oncology Group (ECOG) performance status of 0; 42,1 % had a status of 1; 3,9 % had a status above 1. The median cumulative RAI activity administered prior to study entry was 350 mCi (12.95 GBq).

A statistically significant prolongation in PFS was demonstrated in LENVIMA-treated patients compared with those receiving placebo ($p < 0,0001$). The positive effect on PFS was similar in the subgroups that received 0 or 1 prior VEGF/VEGFR-targeted therapy (see Table 11). In addition, the positive effect on PFS was seen across the subgroups of age, sex, race, histological subtype, and geographic region. Following independent review confirmation of disease progression, 109 (83,2 %) patients randomised to placebo crossed over to receive open-label LENVIMA.

There was no statistically significant difference in overall survival in the treatment arm compared to the placebo group at the primary analysis (HR (95 % CI): 0,73 (0,59, 1,07)). However, the SELECT study was not powered to demonstrate an improvement in OS, and the high rate of crossover of patients in the placebo arm to the treatment arm after confirmed disease progression made demonstration of a statistically significant difference in OS difficult.

The median time to first dose reduction was 2.8 months. The median time to objective response was 2.0 (95 % CI: 1,9; 3,5) months; however, of the patients who experienced a complete or partial response to LENVIMA, 70,4 % were observed to develop the response on or within 30 days of being on the 24-mg dose.

The study did not measure quality of life (QoL). The effect of treatment on QoL can therefore not be assessed and QoL may not be improved with LENVIMA treatment.

Table 11 Efficacy Results in radioactive iodine refractory differentiated thyroid cancer

| | LENVIMA N=261 | Placebo N=131 |
|---|--------------------------|--------------------------|
| Progression-Free Survival (PFS)^a | | |
| Number of progressions or deaths (%) | 107 (41,0) | 113 (86,3) |

| Hazard Ratio (95 % CI) ^{b,e} | 0,73 (0,50; 1,07) | |
| P-value ^{b,e} | 0,1032 | |

CI, confidence interval; NE, not estimable; OS, overall survival; PFS, progression-free survival; RPSFT, rank preserving structural failure time model; VEGF/VEGFR, vascular endothelial growth factor /vascular endothelial growth factor receptor.

- a) Independent radiologic review.
- b) Stratified by region (Europe vs. North America vs. Other), age group (≤ 65 years vs >65 years), and previous VEGF/VEGFR-targeted therapy (0 vs. 1).
- c) Estimated with Cox proportional hazard model.
- d) Estimated using the Kaplan-Meier method; the 95 % CI was constructed with a generalised Brookmeyer and Crowley method in patients with a best overall response of complete response or partial response.
- e) Not adjusted for crossover effect.

Figure 1 Kaplan-Meier Curve of Progression-Free Survival - DTC

A multicentre, randomised, open-label, trial was conducted to determine the safety and efficacy of LENVIMA administered alone or in combination with everolimus in subjects with unresectable advanced or metastatic Renal Cell Carcinoma (RCC). The study consisted of a Phase 1b dose finding and a Phase 2 portion. The Phase 1b portion included 11 patients who received the combination of 18 mg of LENVIMA plus 5 mg of everolimus. The Phase 2 portion enrolled a total of 153 patients with unresectable advanced or metastatic RCC, who had previously received 1 prior VEGF-targeted treatment, 1:1:1 to LENVIMA 18 mg plus everolimus 5 mg, LENVIMA 24 mg monotherapy, or everolimus 10 mg monotherapy. All medications were administered orally once daily. Patients were required to have histological confirmation of predominant clear cell RCC, and ECOG Performance Status of 0 or 1. Patients were stratified by haemoglobin level (≤ 13 g/dL vs. > 13 g/dL for males and ≤ 11.5 g/dL vs > 11.5 g/dL for females) and corrected serum calcium (≥ 10 mg/dL vs. < 10 mg/dL).

Of the 101 patients randomly allocated to the LENVIMA plus everolimus arm and everolimus monotherapy, 72 % were male, the median age was 60 years, 31 % were 65 years or older, and 96 % were Caucasian. All patients were classified as having Stage IV RCC. All patients had a baseline ECOG PS of either 0 (54 %) or 1 (46 %) with similar distribution across the 2 treatment arms. Memorial Sloan Kettering Cancer Center (MSKCC) favourable, intermediate, and poor risk categories were observed respectively, in 24 %, 37 %, and 39 % of patients in the LENVIMA plus everolimus arm, and 24 %, 38 %, and 38 % of patients in the everolimus arm.

The primary efficacy outcome measure was investigator assessed PFS evaluated according to RECIST 1.1. Efficacy results are summarised in Table 12 and Figure 2 and Figure 3. The treatment effect of the combination on PFS was supported by a retrospective independent blinded review of radiographs with an observed hazard ratio (HR) of 0,43 (95 % CI: 0,24, 0,75) compared with the everolimus arm.

Table 12 Efficacy results in renal cell carcinoma (investigator assessment)

| | LENVIMA 18 mg + Everolimus 5 mg (N=51) | Everolimus10 mg (N=50) |
|---|---|-----------------------------------|

Tumour assessments were based on RECIST v1.1 criteria for progression but only confirmed responses are included for ORR.

CI = confidence interval

a Point estimates are based on Kaplan-Meier method and 95% CIs are based on the Greenwood formula using log-log transformation.

b Data cutoff date = 13 Jun 2014

c Hazard ratio is based on a stratified Cox regression model including treatment as a covariate factor and haemoglobin and corrected serum calcium as strata.

d Data cutoff date = 31 Jul 2015

Figure 2 Kaplan-Meier Curve of Progression-Free Survival (Investigator Assessment - RCC)

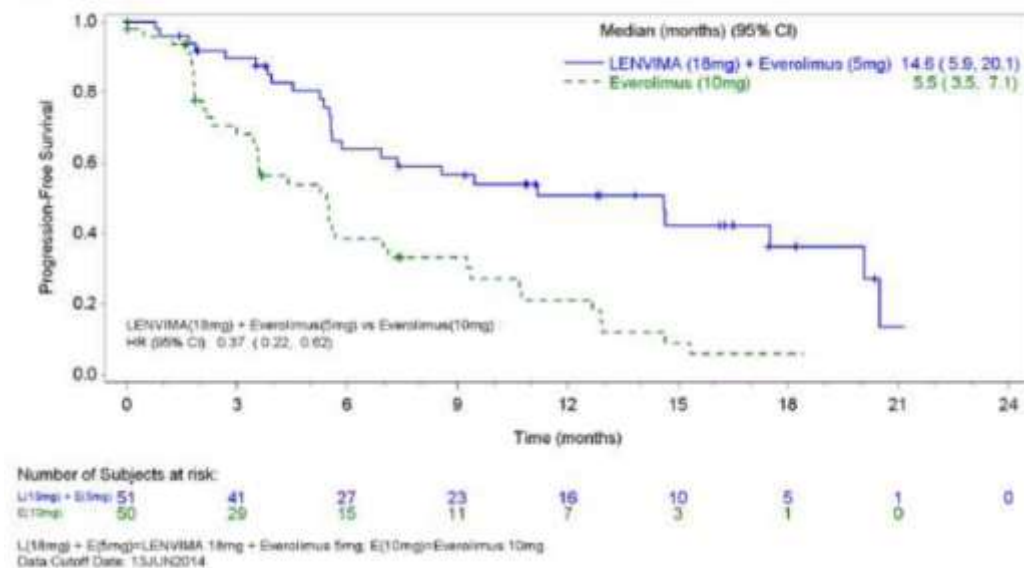

Figure 3 Kaplan-Meier Curve of Overall Survival - RCC

Hepatocellular Carcinoma

A multicenter, open-label study was conducted in 954 patients with unresectable hepatocellular carcinoma who were randomized to LENVIMA or sorafenib. The starting dose of LENVIMA, given once daily, was based on

baseline body weight: 12 mg for patients with a body weight ≥ 60 kg and 8 mg for patients with a body weight < 60 kg. The dose of sorafenib was 400 mg given orally twice daily.

Patients were required to have a histologically or cytologically confirmed diagnosis of unresectable HCC, or a clinically confirmed diagnosis of HCC according to the American Association for the Study of Liver Diseases criteria, including cirrhosis of any etiology, or with chronic hepatitis B or C infection. Patients could have BCLC stage B or C disease and could only have Child Pugh category A liver dysfunction (i.e., a score of 5-6). Patients had at least 1 measurable target hepatic or non-hepatic lesion according to mRECIST, and adequate liver, bone marrow, blood coagulation, renal, and pancreatic function. Patients were stratified by region, presence or absence of macroscopic portal vein invasion (MPVI) or extrahepatic spread (EHS) or both, Eastern Cooperative Oncology Group Performance Status (ECOG PS) 0 or 1, and BW (< 60 kg or ≥ 60 kg). The majority of patients in both treatment arms had an ECOG PS of 0 at Baseline (63 %), Child-Pugh score of 5 (76 %), and weighed ≥ 60 kg (69 %). The median age was 62 years, 84 % were male, 16 % were female, 69 % were Asian, 1 % were black, and 29 % were white. Approximately 80 % of patients in Study 304 had BCLC stage C disease at study entry. This percentage was similar between the treatment arms (LENVIMA 374/478, 78,2 %; sorafenib 384/476, 80,7 %).

LENVIMA was non-inferior for Overall Survival (OS) to sorafenib. Median OS was 13,6 months compared to 12,3 months for sorafenib with HR = 0,92 [95 % CI of (0,79; 1,06)].

Based on investigator assessment evaluated according to mRECIST, LENVIMA treatment resulted in statistically significant ($P < 0,00001$) and clinically meaningful improvement over sorafenib in the secondary endpoints of PFS and ORR. LENVIMA treatment significantly prolonged TTP compared to sorafenib, with a median TTP that was more than twice as long as that of sorafenib. Retrospective independent review of imaging corroborated the secondary endpoints of PFS, TTP and ORR. These efficacy results are summarised in Table 13 and Figure 4, Figure 5 and Figure 6.

| Table 13 Efficacy Results in Hepatocellular Carcinoma | | |
|--|-----------------------------|------------------------------|

| P-value ^g | <0,00001 | |

Data cutoff date: 13 Nov 2016.

The noninferiority margin for the HR of LENVIMA versus sorafenib is 1,08. Percentages are based on the total number of subjects within the relevant treatment group in the Full Analysis Set.

CI = confidence interval; ECOG PS = Eastern Cooperative Oncology Group Performance Status; HR = hazard ratio; OS = overall survival

a Quartiles are estimated by the Kaplan-Meier method, and the 95 % CIs are estimated with a generalised Brookmeyer and Crowley method.

b Hazard ratio is for LENVIMA vs. sorafenib, based on a Cox model including treatment group as a factor.

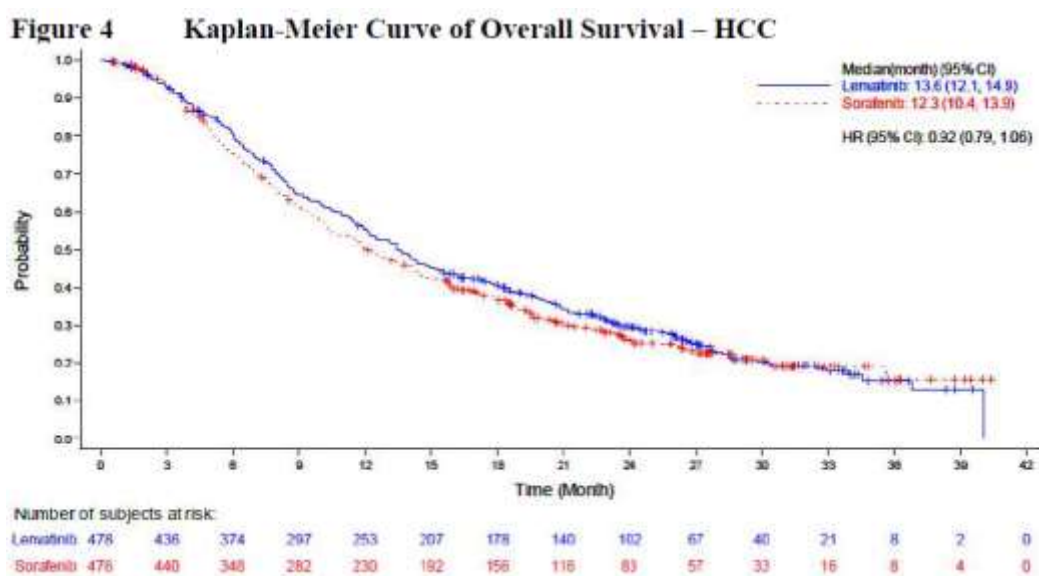

c Stratified by region (Region 1: Asia-Pacific; Region 2: Western regions), macroscopic portal vein invasion or extrahepatic spread or both (yes, no), ECOG PS (0, 1) and body weight (<60 kg, ≥60 kg).

d P-value is for the superiority test of LENVIMA versus sorafenib.

e Deaths were not counted as progression events in this analysis.

f 95 % CI was calculated using asymptotic normal approximation.

g Odds ratio and P-value (for superiority test) were calculated using the Cochran-Mantel-Haenszel method, stratified by IxRS stratification factors.

Data cutoff date = 13 Nov 2016.

Noninferiority margin for hazard ratio (HR: LENVIMA vs sorafenib = 1.08).

Median was estimated with the Kaplan-Meier method and the 95 % confidence interval was constructed with a generalised Brookmeyer and Crowley method.

HR was estimated from the Cox proportional hazard model with treatment as independent variable and stratified by IxRS stratification factors. The Efron method was used for ties.

+ = censored observations

CI = confidence interval; HR = hazard ratio; IxRS = interactive response system.

Figure 5 Kaplan-Meier Curve of Progression-free Survival – HCC

Data cutoff date = 13 Nov 2016.

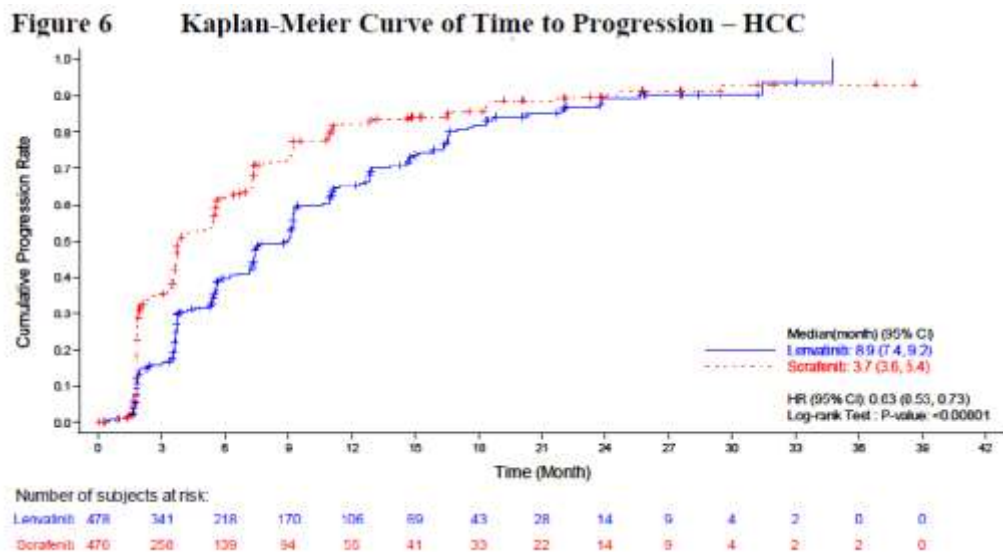

Median was estimated with the Kaplan-Meier method and the 95 % CI was constructed with a generalized Brookmeyer and Crowley method.

Hazard ratio is expressed as LENVIMA: sorafenib and was estimated from the Cox proportional hazard model with treatment as an independent variable and stratified by IxRS stratification factors. The Efron method was used for ties.

P-value was for superiority test (LENVIMA vs. Sorafenib) and was calculated using log-rank test stratified by IxRS stratification factors.

+ = censored observations.

CI = confidence interval; HR = hazard ratio; IxRS = interactive response system.

Data cutoff date: 13 Nov 2016.

The median was estimated using the Kaplan-Meier method and the 95 % CI was constructed with a generalized Brookmeyer and Crowley method.

Hazard ratio is expressed as LENVIMA: sorafenib and was estimated from the Cox proportional hazard model with treatment as an independent variable and stratified by IxRS stratification factors. Efron method was used for ties.

P-value is for the superiority test of LENVIMA vs sorafenib and was calculated using the log-rank test stratified by IxRS stratification factors.

CI = confidence interval; HR = hazard ratio; IxRS = interactive voice/web response system.

Assessment on Quality of Life (QoL) in Patients with HCC

Three QoL questionnaires were administered EORTC QLQ-C30, EORTC QLQ-HCC18 and the EQ-5D-3L.

Compared to patients treated with LENVIMA, those treated with sorafenib experienced greater risks of more rapid time to clinically meaningful worsening of symptoms and function for the domain of Diarrhoea (nominal $p < 0,0001$) from the EORTC QLQ-C30.

5.2 Pharmacokinetic properties

Absorption

Lenvatinib is rapidly absorbed after oral administration with T_{max} typically observed from 1 to 4 hours post-dose. Food does not affect the extent of absorption but slows the rate of absorption. When administered with food to healthy subjects, peak plasma concentrations are delayed by 2 hours.

A high degree of inter-individual variability in average exposure at steady state was observed, with a 6-fold range when used as monotherapy at the 24 mg dose, and 7-fold range when LENVIMA 18 mg dose is administered in combination with 5mg everolimus. In HCC subjects, the inter-individual variability in average exposure at steady state was 6-fold and 5-fold range when used as monotherapy at 8 mg and 12 mg doses, respectively.

Distribution

In vitro binding of lenvatinib to human plasma proteins was high and ranged from 98 % to 99 % (0.3 – 30 µg/mL, mesilate). This binding was mainly to albumin with minor binding to α 1-acid glycoprotein and γ -globulin.

In vitro, the lenvatinib blood-to-plasma concentration ratio ranged from 0,589 to 0,608 (0,1 - 10 µg/mL, mesilate).

In vitro studies indicate that lenvatinib is a substrate for P-gp and BCRP. Lenvatinib is not a substrate for OAT1, OAT3, OATP1B1, OATP1B3, OCT1, OCT2, MATE1, MATE2-K or the BSEP.

Metabolism

In vitro, cytochrome P450 3A4 was the predominant (>80 %) cytochrome isoform involved in the P450- mediated metabolism of lenvatinib. *In vivo*, inducers and inhibitors of CYP 3A4 had a minimal effect on lenvatinib exposure (see section 4.5). Patients should avoid strong inducers of CYP 3A4 and exercise caution with mild or moderate inhibitors or inducers when using everolimus (see Everolimus Product Information) in combination with LENVIMA.

In human liver microsomes, the demethylated form of lenvatinib (M2) was identified as the main metabolite. M2' and M3', the major metabolites in human faeces, were formed from M2 and lenvatinib, respectively, by aldehyde oxidase.

In plasma samples collected up to 24 hours after administration, lenvatinib constituted 97 % of the radioactivity in plasma radiochromatograms while the M2 metabolite accounted for an additional 2,5 %. Based on AUC (0–inf), lenvatinib accounted for 60 % and 64 % of the total radioactivity in plasma and blood, respectively.

Data from a human mass balance/excretion study indicate lenvatinib is extensively metabolised in humans. The main metabolic pathways in humans were identified as oxidation by aldehyde oxidase, demethylation via CYP3A4, glutathione conjugation with elimination of the O-aryl group (chlorbenzyl moiety), and combinations of these pathways followed by further biotransformations (eg, glucuronidation, hydrolysis of the glutathione moiety, degradation of the cysteine moiety, and intramolecular rearrangement of the cysteinylglycine and cysteine conjugates with subsequent dimerisation). These *in vivo* metabolic routes align with the data provided in the *in vitro* studies using human biomaterials.

Elimination

Plasma concentrations decline bi-exponentially following C_{max} . The mean terminal exponential half-life of lenvatinib is approximately 28 hours.

Following administration of radiolabelled lenvatinib to 6 patients with solid tumours, approximately two-thirds and one-fourth of the radiolabel were eliminated in the faeces and urine, respectively. The M2 metabolite was the predominant analyte in excreta (~5 % of the dose) with lenvatinib the second most prominent (~2,5 %).

Linearity/non-linearity

Dose proportionality and accumulation

In patients with solid tumours administered single and multiple doses of lenvatinib once daily, exposure to lenvatinib (C_{max} and AUC) increased in direct proportion to the administered dose over the range of 3,2 to 32 mg once-daily (QD).

Lenvatinib displays minimal accumulation at steady state. Over this range, the median accumulation index (Rac) ranged from 0,96 (20 mg) to 1,54 (6,4 mg). In patients with HCC, the mean accumulation ratio was 1.49 in those with higher Child-Pugh scores (7-8) receiving 8 mg lenvatinib.

Special populations

Hepatic impairment

The pharmacokinetics of lenvatinib following a single 10-mg dose were evaluated in 6 subjects each with mild or moderate hepatic impairment (Child-Pugh A and Child-Pugh B, respectively). A 5-mg dose was evaluated in 6 subjects with severe hepatic impairment (Child-Pugh C). Eight healthy, demographically matched subjects served as controls and received a 10-mg dose. The median half-life was comparable in subjects with mild, moderate, and severe hepatic impairment as well as those with normal hepatic function and ranged from 26 hours to 31 hours. The percentage of the dose of lenvatinib excreted in urine was low in all cohorts (< 2,16 % across treatment cohorts).

Lenvatinib exposure, based on dose-adjusted AUC_{0-t} , unbound and AUC_{0-inf} , unbound, was approximately 65 %, 122 %, and 273 % of normal for subjects with mild, moderate, and severe hepatic impairment, respectively. Based on the analogous AUC_{0-t} and AUC_{0-inf} data, lenvatinib exposure was 119 %, 107 %, and 180 % of normal for subjects with mild, moderate, and severe hepatic impairment, respectively (see section 4.2).

Renal impairment

The pharmacokinetics of lenvatinib following a single 24 mg dose were evaluated in 6 subjects each with mild, moderate, or severe renal impairment, and compared with 8 healthy, demographically matched subjects. Subjects

with end-stage renal disease were not studied. The percentage of unbound lenvatinib was similar between subjects with normal renal function ($8\% \pm 3\%$, mean \pm SD) and those with severely impaired renal function ($9\% \pm 2\%$). $AUC_{0-\infty}$, unbound estimates for subjects with mild, moderate, or severe renal impairment were 54 %, 129 %, and 184 %, respectively, compared with normal subjects. Additionally, a linear equation was fit to the creatinine clearance vs. $AUC_{0-\infty}$, unbound data and exposure was predicted. Subjects with severe renal impairment were predicted to have a 2,4-fold increase in exposure. Therefore, dosage needs to be reduced in DTC and RCC patients with severe renal impairment (see section 4.2). No dosage recommendations are available for HCC patients with severe renal impairment (see section 4.2). Use in HCC patients with severe renal impairment is not recommended.

Age, sex, weight, race

Based on a population pharmacokinetic analysis of patients receiving up to 24 mg LENVIMA once daily, including HCC patients weighing < 60 kg and ≥ 60 kg receiving 8 mg and 12 mg, respectively, weight showed a statistically significant effect. The final PK model for lenvatinib included body-weight effect as an allometric constant on both clearance (CL/F) and volume parameters, whereby parameters increased with increasing body weight. The decrease in CL/F in subjects with low body weight resulted in an increase in lenvatinib exposure (AUC) whereby subjects weighing < 60 kg had approximately 35 % higher exposure to lenvatinib than subjects weighing ≥ 60 kg when receiving the same dose. Based on the individual lenvatinib AUC at steady state for subjects with HCC, the median value and range of AUC are comparable between the group of starting dose of 8 mg for body weight < 60 kg and 12 mg for body weight ≥ 60 kg, which supports the starting doses of 8 mg and 12 mg for body weight < 60 kg and ≥ 60 kg, respectively, in HCC patients.

After accounting for body weight, neither age, sex, or race (Japanese vs. other, Chinese vs other, white vs. other) influenced lenvatinib PK.

Paediatric Population

Paediatric patients have not been studied.

Genomic assessment of lenvatinib pharmacokinetic parameters

Because of lenvatinib's extensive metabolism, the effect of selected drug-metabolising enzyme phenotypes on lenvatinib clearance was investigated using data derived from the Affymetrix drug-metabolising enzyme and transporter (DMET Plus) microarray genotyping platform. None of the phenotypes for CYP3A5, CYP1A2, CYP2A6, or CYP2C19 had a significant impact on lenvatinib clearance.

5.3 Preclinical safety data

Genotoxicity

Lenvatinib was not mutagenic in the *in vitro* Ames and mouse lymphoma tests and not clastogenic in an *in vivo* micronucleus assay in rats. These studies indicate a low genotoxic potential for LENVIMA.

Carcinogenicity

Carcinogenicity studies have not been conducted with LENVIMA.

6. PHARMACEUTICAL PARTICULARS

6.1 List of excipients

Capsule

Calcium carbonate

Hydroxypropylcellulose

Low-substituted hydroxypropylcellulose

Mannitol

Microcrystalline cellulose

Purified talc

Capsule shell

Hypromellose

Iron oxide red

Iron oxide yellow

Titanium dioxide

Printing ink

Iron oxide black (E172)

Potassium hydroxide

Propylene glycol

Shellac

6.2 Incompatibilities

Incompatibilities were either not assessed or not identified as part of the registration of this medicine.

6.3 Shelf life

4 years

6.4 Special precautions for storage

Store at or below 30 °C.

Store in the original container until required for use.

6.5 Nature and contents of container

LENVIMA 4 mg hard capsules are available in polyamide/aluminium/PVC/aluminium blisters of 30 capsules.

LENVIMA 10 mg hard capsules are available in polyamide/aluminium/PVC/aluminium blisters of 30 capsules.

The LENVIMA capsules are furthermore packaged in a carton board.

6.6 Special precautions for disposal and other handling

Any unused medicine or waste material should be disposed of in accordance with local requirements.

Do not open the capsule. Caregivers should avoid repeated exposure to the contents of the capsule.
